

# Ordinary Differential Equations and Dynamical Systems

## Part I

## Modeling

### Fundamentals

Formally, an ordinary differential equation is an equation, in which a function and its derivatives and the independent variable appear.

An (implicit) *ordinary differential equation* of order  $n$  is an equation of the form

$$F(x, y, y', y'', \dots, y^{(n)}) = 0. \quad (1)$$

An example of an explicit ODE of order  $n$  is of the form

$$y^n = G(x, y, y', y'', \dots, y^{n-1}). \quad (2)$$

### Classification

Differential equations can be classified according to various criteria. Besides the order of an ODE we are also interested in whether an ODE is linear, homogeneous, has constant coefficient, is separable or autonomous.

#### Linearity

An  $n$ -th order ODE is *linear*, if it is of the form:

$$a_n(x) \cdot y^{(n)} + \dots + a_1(x) \cdot y' + a_0(x) \cdot y = g(x) \quad (3)$$

where  $a_n(x), \dots, a_1(x), a_0(x)$  are  $g(x)$  fixed functions. Or in other words: A differential equation is linear if the dependant variable and all of its derivatives appear in a linear fashion (i.e., they are not multiplied together or squared for example or they are not part of transcendental functions such as sins, cosines, exponentials, etc.)

#### Homogeneity

A linear ODE is *homogeneous*, if  $g(x) = 0$  for all  $x$ ; otherwise the ODE is *inhomogeneous*, and  $g(x)$  is the *inhomogeneity* or *source* term.

#### Constant coefficient

A linear ODE has *constant coefficients*, if it is of the form

$$a_n \cdot y^{(n)} + \dots + a_1 \cdot y' + a_0 \cdot y = g(x), \quad (4)$$

with  $a_n \neq 0$  (the source term  $g(x)$  does not have to be constant).

#### Separability

The ODE is *separable*, if  $F(x, y)$  can be written as a product of a  $x$ - and  $y$ -dependent term, i.e. if the ODE is of the form

$$y' = g(x) \cdot h(y) \quad (5)$$

#### Autonomy

The ODE (1.28) is *autonomous*, if  $F(x, y)$  only depends on  $y$ , i.e. if the ODE is of the form

$$y' = h(y) \quad (6)$$

Every autonomous ODE is separable with  $g(x) = 1$ .

#### Examples

$y' = f(x)$	Inhomogeneous linear ODE for $y(x)$ with source term $f(x)$
$m \cdot \dot{v} = m \cdot g - k \cdot v^2$	Nonlinear ODE for $v(t)$
$l \cdot \ddot{\Phi} + g \cdot \sin(\Phi) = 0$	Nonlinear ODE for $\Phi(t)$
$l \cdot \ddot{\Phi} + g \cdot \phi$	Homogeneous linear ODE for $\Phi(t)$
$l \cdot \ddot{\Phi} + g \cdot \phi = \sin(\omega t)$	Inhomogeneous linear ODE for $\Phi(t)$ with source term $\sin(\omega t)$
$i'' + \frac{R}{L}i' + \frac{1}{LC}i = 0$	Homogeneous linear ODE for $i(t)$

### Systems of differential equations

If several systems are coupled with each other and mutually influence each other, one often obtains a system of ODE's.

A *system of differential equations* of first order is a system

$$\begin{aligned} y_1' &= f_1(x, y_1, \dots, y_n) \\ &\vdots \\ y_n' &= f_n(x, y_1, \dots, y_n) \end{aligned} \quad (7)$$

of ODE's for unknown functions  $y_1(x), \dots, y_n(x)$ .

Using the vectorial notation

$$\mathbf{y}' = \mathbf{f}(x, \mathbf{y}) \quad (8)$$

An ODE of  $n$ -th order is equivalent to a system of first-order ODE's.

$$\begin{aligned} y_1' &= y_2 \\ y_2' &= y_3 \\ &\vdots \\ y_n' &= f(x, y_1, \dots, y_n) \end{aligned} \quad (9)$$

**Example: 2nd-order ODE to system of first-order ODE's**

We want to rewrite the following 2nd order ODE into a system of first-order ODE's.

$$\ddot{x}(t) + 2\delta\dot{x}(t) + \omega_0^2 x(t) = f(t) \quad (10)$$

If we introduce the vector-valued function

$$\mathbf{y} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} x \\ \dot{x} \end{pmatrix} \Rightarrow \dot{\mathbf{y}} = \begin{pmatrix} \dot{y}_1 \\ \dot{y}_2 \end{pmatrix} = \begin{pmatrix} \dot{x} \\ \ddot{x} \end{pmatrix} \quad (11)$$

rewriting:

$$\begin{aligned} \dot{\mathbf{y}} &= \begin{pmatrix} \dot{x} \\ \ddot{x} \end{pmatrix} = \begin{pmatrix} \dot{x} \\ -2\delta\dot{x}(t) - \omega_0^2 x(t) + f(t) \end{pmatrix} \\ \dot{\mathbf{y}} &= \begin{pmatrix} \dot{x} \\ \ddot{x} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -\omega_0^2 & -2\delta \end{pmatrix} \begin{pmatrix} x \\ \dot{x} \end{pmatrix} + \begin{pmatrix} 0 \\ f(t) \end{pmatrix} \\ \dot{\mathbf{y}} &= \mathbf{A}\mathbf{y} + \mathbf{b} \end{aligned} \quad (12)$$

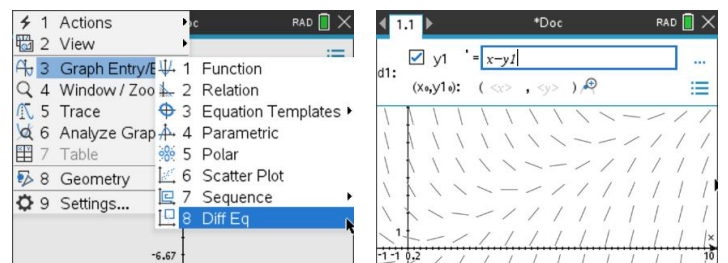

### Slope field

Slope fields are often lead to a good qualitative understanding of the situation described by the ODE under consideration. Slope field can be understood in the following way: To each point  $(x, y)$  in the region  $B$  under consideration,  $F(x, y)$  is a value which describes the slope of the solution curve passing through the point  $(x, y)$ .

#### Example with calculator

We want to plot the slope field of the following ODE

$$y' = x - y \quad (13)$$

Select: Menu, 3: Graph Entry/Edit, 8: Diff Eq.

Write down the ODE

### Solvability

Two solution curves of an ODE cannot cross.

## Part II

## Ordinary Differential Equations

### Analytical methods for first-order ODE's

#### Overview

Separable ODE's  
Linear ODE's  
Exact ODE's

## Separable ODE's

### Example

We compute the general solution of the ODE

$$y' = -\frac{x}{y} \quad (14)$$

- We write the equation as

$$\frac{dy}{dx} = -\frac{x}{y} \quad (15)$$

-We bring all  $x$ -dependent terms to the left hand side and all  $y$ -dependent terms on the right hand side:

$$y \, dy = -x \, dx \quad (16)$$

-We integrate on both sides and get

$$\int y \, dy = -\int x \, dx \Rightarrow \frac{1}{2}y^2 = -\frac{1}{2}x^2 + C, \quad C \in \mathbb{R} \quad (17)$$

- We solve for  $y$  and get

$$y = \pm \sqrt{K - x^2}, \quad K \in \mathbb{R} \quad (\text{where } K = 2C) \quad (18)$$

### Example of substitution

We consider the ODE

$$y' = (x + y)^2 \quad (19)$$

## Exact ODE's

## Analytical methods for linear ODE's

### Overview

We differentiate between first-order linear ODE's and higher-order ODE's as well as between homogeneous and inhomogeneous ODE's.

The general solution of the inhomogeneous ODE is the sum

$$y = y_h + y_s, \quad (20)$$

where  $y_h$  is the general solution of the homogeneous ODE and  $y_s$  any special solution of the inhomogeneous ODE.

### First-order linear ODE's

To solve a first-order linear ODE we thus have to find  $y_h$  and  $y_s$

**$y_h$ :** a homogeneous first-order ODE is separable and can therefore be solved by the standard procedure for separable ODE's described above.

**$y_s$ :** To find a special solution of an ODE, there are several possibilities. In the case of an ODE with constant coefficients, it usually suffices to choose for  $y_s$  an *ansatz of the form of the source term*  $g(x)$ . In the case of non-constant coefficients, the method *variation of constants* usually works better.

### Example using the ansatz

We solve the ODE

$$y' + ay = b \quad (21)$$

- To determine  $y_h$ , we integrate the homogeneous ODE

$$y' + ay = 0 \quad (22)$$

by separation of variables we obtain the solution

$$y_h = C \cdot e^{-ax}, \quad C \in \mathbb{R}. \quad (23)$$

- For finding  $y_s$  we choose the ansatz in the form of the source term. In this case the source term is constant,  $g(x) = b$ . Therefore we assume that the special solution  $y_s$  is constant as well, i.e. we make an ansatz  $y_s = c$ . We plug this ansatz into the inhomogeneous ODE and obtain the special solution  $y_s$ .

$$y'_s + ay_s = b \Rightarrow y_s = \frac{a}{b} \quad (24)$$

The general solution therefore is

$$y = C \cdot e^{-ax} + \frac{a}{b}, \quad C \in \mathbb{R} \quad (25)$$

### Ansatz functions for the solution of the inhomogeneous first-order ODE

Source term  $g(x)$

$$g(x) = b_0$$

$$g(x) = b_1x + b_0$$

$$g(x) = b_2x^2 + b_1x + b_0$$

$$g(x) = \sum_{i=0}^n b_i x^i$$

$$g(x) = A \sin(\omega x) + B \cos(\omega x)$$

$$g(x) = Ae^{bx}$$

Ansatz  $y_s$

$$y_s = c_0$$

$$y_s = c_1x + c_0$$

$$y_s = c_2x^2 + c_1x + c_0$$

$$y_s = \sum_{i=0}^n c_i x^i$$

$$y_s = C_1 \sin(\omega x) + C_2 \cos(\omega x)$$

$$y_s = C \sin(\omega x + \varphi)$$

$$y_s = \begin{cases} \frac{A}{b+a} e^{bx} & \text{for } b \neq -a \\ Axe^{-ax} & \text{for } b = -a \end{cases}$$

In addition, the following rules must be followed:

**Linearity** If  $g(x)$  is a linear combination of several source terms, one has to assume as ansatz for  $y_s(x)$  a corresponding linear combination of several ansatz terms.

**Resonance** If the source term  $g(x)$  is itself already a solution of the homogeneous ODE, the corresponding ansatz for  $y_s$  has to be multiplied with  $x$ . So if for example  $y_h = Ce^x$ , and  $g(x) = e^x$ , the ansatz  $y_s = x \cdot e^x$  is chosen.

### Example using Variation of constants

The idea behind the variation of constants is to start from the solution  $y = K \cdot e^{-F(x)}$  of the homogeneous ODE and plug the ansatz

$$y = K(x) \cdot e^{-F(x)} \quad (26)$$

into the inhomogeneous ODE.

As an example we want to solve the inhomogeneous linear ODE

$$3y' + 5y = 7e^{\frac{1}{3}x}. \quad (27)$$

- We first find the homogeneous solution  $y_h$  by separation of variables.

$$\frac{1}{y} dy = -\frac{5}{3} x \, dx \Rightarrow y_h = e^{\frac{5}{3}x} \cdot K \quad (28)$$

- Next we calculate the ansatz and its derivative

$$y_s = e^{-\frac{5}{3}x} \cdot K(x) \quad (29)$$

$$y'_s = K(x)' e^{-\frac{5}{3}x} + K(x) \cdot \left(-\frac{5}{3}\right) e^{-\frac{5}{3}x}$$

- The ansatz is then plugged into the inhomogeneous ODE

$$3 \left( K(x)' e^{-\frac{5}{3}x} + K(x) \cdot \left(-\frac{5}{3}\right) e^{-\frac{5}{3}x} \right) + 5 \left( e^{-\frac{5}{3}x} \cdot K(x) \right) = 7e^{\frac{1}{3}x} \quad (30)$$

- We solve for  $K(x)'$  ( $K(x)$  usually disappears)

$$3 \cdot K(x)' e^{-\frac{5}{3}x} = 7e^{\frac{1}{3}x} \Rightarrow K(x)' = \frac{7}{3} e^{\frac{1}{3}x + \frac{5}{3}x} = \frac{7}{3} e^{2x} \quad (31)$$

- We integrate and find  $K(x)$

$$K(x) = \frac{7}{6} e^{2x} \quad (32)$$

- Plug in  $K(x)$  into the ansatz we get the special solution  $y_s$

$$y_s = e^{-\frac{5}{3}x} \cdot \frac{7}{6} e^{2x} = \frac{7}{6} e^{\frac{1}{3}x} \quad (33)$$

- The solution  $y_h + y_s$  is then

$$y = K \cdot e^{-\frac{5}{3}x} + \frac{7}{6} e^{\frac{1}{3}x} \quad (34)$$

If the problem is an initial value problem; plug in values for  $x$  and  $y$  and solve for  $K$ .

## Higher-order linear ODE's

The fact that the solution of an inhomogeneous ODE is the sum of the solution of the homogeneous ODE and the special solution (equation 20) still holds true for higher-order linear ODE's

### The homogeneous case

The function  $y = e^{\lambda x}$  is a solution of the homogeneous ODE if and only if  $\lambda$  is a root of the characteristic polynomial, i.e. if

$$P(\lambda) = 0 \quad (35)$$

We now have to distinguish between real and complex and between single and multiple roots of the characteristic polynomial.

**Real Roots** If  $\lambda$  is a real root of  $P(\lambda)$  of multiplicity  $m$ , then the functions

$$y_1 = e^{\lambda x}, y_2 = x e^{\lambda x}, \dots, y_m = x^{m-1} e^{\lambda x} \quad (36)$$

are distinct linearly independent solutions. i.e. if  $m = 1$  and  $\lambda$  is a simple root then  $y = C_1 e^{\lambda x}$  is the solution.

Example: The homogeneous ODE

$$y^{(3)} - 3y'' - 4y' = 0 \quad (37)$$

has the characteristic polynomial

$$P(\lambda) = \lambda^3 - 3\lambda^2 - 4\lambda. \quad (38)$$

The roots of this polynomial are  $\lambda_1 = 0, \lambda_2 = 4, \lambda_3 = -1$ , hence the general solution of the ODE is

$$y = C_1 + C_2 e^{4x} + C_3 e^{-x} \quad (39)$$

**Complex Roots** If  $\lambda = \alpha \pm j\beta$  are two complex roots of  $P(\lambda)$  of multiplicity  $m$  then

$$\begin{array}{ll} y_1 = e^{\alpha x} \cos(\beta x) & y_2 = e^{\alpha x} \sin(\beta x) \\ y_3 = x e^{\alpha x} \cos(\beta x) & y_4 = x e^{\alpha x} \sin(\beta x) \\ \vdots & \vdots \\ y_{2m-a} = x^{m-1} e^{\alpha x} \cos(\beta x) & y_{2m} = x^{m-1} e^{\alpha x} \sin(\beta x) \end{array}$$

are  $m$  linearly independent solutions.

If  $m = 1$  and  $\lambda_{1,2} = \alpha \pm j\beta$  then  $y_1 = C_1 e^{\alpha x} \cos(\beta x)$  and  $y_2 = C_2 e^{\alpha x} \sin(\beta x)$  are two linearly independent solutions.

Example: The homogeneous ODE

$$y'' + y = 0 \quad (40)$$

has the characteristic polynomial

$$P(\lambda) = \lambda^2 + 1. \quad (41)$$

The roots of this polynomial are  $\lambda_1 = j, \lambda_2 = -j$ , hence the general solution of the ODE is

$$y = C_1 \cos(x) + C_2 \sin(x) \quad (42)$$

### The inhomogeneous case

We now determine special solutions of the inhomogeneous ODE's. The best method for solving such ODE's is as above using an ansatz of the form of the source term, with undetermined coefficients. These coefficients are then determined by plugging the ansatz into the equation.

Example: Consider the inhomogeneous ODE

$$y^{(3)} + y'' + y' + y = 2x + 5 \quad (43)$$

The general solution of the homogeneous ODE is (The complex roots are  $-1, -j, j$ )

$$y_h = C_1 e^{-x} + C_2 \cos(x) + C_3 \sin(x) \quad (44)$$

To find a special solution of the inhomogeneous ODE, we choose the ansatz

$$y_s = b_1 x + b_0 \quad (45)$$

Plugin this into the initial ODE leads to

$$b_1 + (b_1 x + b_0) = 2x + 5 \quad (46)$$

which leads to the following linear system of equations for  $a$  and  $b$

$$\begin{vmatrix} b_1 & = & 2 \\ b_1 + b_0 & = & 5 \end{vmatrix} \Rightarrow b_1 = 2, \quad b_0 = 3 \quad (47)$$

The desired special solution hence is

$$y_s = 2x + 3 \quad (48)$$

and the general solution therefore is

$$y = C_1 e^{-x} + C_2 \cos(x) + C_3 \sin(x) + 2x + 3 \quad (49)$$

## Numerical Methods

### Single-setp methods

## Part III

# System of Differential Equations

### Analytical methods for linear systems

By the definition given above, by a system of ODE's we mean the following system of explicit firstorder ODE's:

$$\begin{array}{ll} \dot{x}_1 & = f_1(t, x_1, \dots, x_n) \\ \vdots & \vdots \\ \dot{x}_n & = f_n(t, x_1, \dots, x_n) \end{array} \quad (50)$$

## Overview

A system of linear first-order ODE's has the form

$$\begin{array}{ll} \dot{x}_1 & = a_{11}(t)x_1 + \dots + a_{1n}(t)x_n + b_1(t) \\ \vdots & \vdots \\ \dot{x}_n & = a_{n1}(t)x_1 + \dots + a_{nn}(t)x_n + b_n(t) \end{array} \quad (51)$$

or in matrix-vector notation

$$\dot{\mathbf{x}} = A(t)\mathbf{x} + \mathbf{b}t \quad (52)$$

The general solution of the inhomogeneous system is the sum

$$\mathbf{x} = \mathbf{x}_h + \mathbf{x}_s \quad (53)$$

where  $x_h$  is the general solution of the homogeneous system and  $x_s$  any special solution of the inhomogeneous system.

The set of solutions of the homogeneous system is an  $n$ -dimensional vector space. This is equivalent to the following two statements:

- Any linear combination of solutions is again a solution, i.e. if  $x_1$  and  $x_2$  are solutions, then  $C_1 x_1 + C_2 x_2$  is also a solution for any  $C_1, C_2 \in \mathbb{R}$
- There exist precisely  $n$  linearly independent solution  $x_1, \dots, x_n$ . Such a set  $\{x_1, \dots, x_n\}$  of linearly independent solutions is also called a *fundamental system of solutions*. Algebraically, a fundamental system thus is a basis of the vector space of solutions.

### Homogeneous linear systems

Since in the scalar case the solution of a homogeneous linear ODE is given by  $x = e^{at}$ , we try in the vectorial case an ansatz of the form

$$\mathbf{x} = e^{\lambda t} \cdot \mathbf{c} = \begin{pmatrix} e^{\lambda t} c_1 \\ \vdots \\ e^{\lambda t} c_n \end{pmatrix} \quad (54)$$

Plugging the ansatz into the ODE leads to  $e^{\lambda t} \lambda \mathbf{c} = e^{\lambda t} A \mathbf{c}$  and we thus get for  $\lambda$  and  $\mathbf{c}$  the equation

$$A \mathbf{c} = \lambda \mathbf{c} \quad (55)$$

This precisely means that  $\mathbf{c}$  is an *eigenvector* of  $A$  to the *eigenvalue*  $\lambda$ . We distinguish between the following cases for  $\lambda$

#### Real eigenvalues

If all eigenvalues of  $A$  are real and  $A$  has  $n$  linear independent eigenvectors then the general solution is a linear combination of

$$\mathbf{x}(t) = e^{\lambda t} \cdot \mathbf{c} \quad (56)$$

Example: We compute the general solution of the homogeneous system

$$\begin{array}{l} \dot{x}_1 = 2x_1 - x_2 \\ \dot{x}_2 = -x_1 + 2x_2 \end{array} \quad (57)$$

or in the form  $\dot{\mathbf{x}} = A \mathbf{x}$  with

$$\mathbf{x}(t) = \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix}, \quad A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \quad (58)$$

The matrix  $A$  has the eigenvalues  $\lambda_1 = 1, \lambda_2 = 3$  with corresponding eigenvectors  $v_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, v_2 = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$ . Hence the general solution  $\mathbf{x}(t)$  of the homogeneous system is

$$\mathbf{x}(t) = \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} = C_1 e^t \begin{pmatrix} 1 \\ 1 \end{pmatrix} + C_2 e^{3t} \begin{pmatrix} 1 \\ -1 \end{pmatrix} \quad (59)$$

#### Complex eigenvalues

If there is at least one pair of complex conjugate eigenvalues and  $A$  has  $n$  linear independent eigenvectors then the general (complex) solution is a linear combination of  $\mathbf{x} = e^{\lambda t} \cdot \mathbf{c}$ . Real and complex parts of complex solutions are real solutions

If  $\lambda = \mu + j\nu$  is a simple complex eigenvalue of  $A$  and  $\mathbf{c} = \mathbf{a} + j\mathbf{b}$  a corresponding complex eigenvector of  $A$ , then from the complex solution

$$\mathbf{x}(t) = e^{\lambda t} \mathbf{c} = e^{(\mu + j\nu)t} (\mathbf{a} + j\mathbf{b}) \quad (60)$$

we get two linearly independent real solutions by separating the complex solution into real and imaginary parts:

$$\begin{aligned}\mathbf{z}_1(t) &= \text{Re}(e^{\lambda t} \mathbf{c}) = e^{\mu t} (\mathbf{a} \cos(\nu t) - \mathbf{b} \sin(\nu t)) \\ \mathbf{z}_2(t) &= \text{Im}(e^{\lambda t} \mathbf{c}) = e^{\mu t} (\mathbf{a} \sin(\nu t) + \mathbf{b} \cos(\nu t))\end{aligned}\quad (61)$$

The complex conjugate of  $\lambda$ , namely  $c = a - jb$  does not have to be considered because it would again lead to the same solutions.  $\mathbf{x}$  is then  $\mathbf{z}_1 + \mathbf{z}_2$  ???

Example: We compute the general solution of a homogeneous system of ODE's where the matrix  $A$  is

$$A = \begin{pmatrix} 3 & -2 \\ 4 & -1 \end{pmatrix} \quad (62)$$

The eigenvalues of  $A$  are  $\lambda_{1,2} = 1 \pm 2j$ , with eigenvectors  $\lambda_{1,2} = \begin{pmatrix} 1 \pm j \\ 2 \end{pmatrix}$ .

$$\mathbf{x} = C_1 e^t \begin{pmatrix} 1 \cos(2t) - 1 \sin(2t) \\ 2 \cos(2t) - 0 \sin(2t) \end{pmatrix} + C_2 e^t \begin{pmatrix} 1 \sin(2t) + 1 \cos(2t) \\ 2 \sin(2t) + 0 \cos(2t) \end{pmatrix} \quad (63)$$

### Polynomial expressions

If  $A$  has multiple eigenvalues and less than  $n$  linear independent eigenvectors (More eigenvalues than eigenvectors), then not all solutions are of the form  $\mathbf{x}(t) = e^{\lambda t} \mathbf{c}$ . Additional solutions involve polynomial expressions. These polynomials are of the form

$$\begin{aligned}p_0(t) &= e^{\lambda t} \mathbf{v}_1 \\ p_1(t) &= e^{\lambda t} (t \mathbf{v}_1 + \mathbf{v}_2) \\ p_2(t) &= e^{\lambda t} (t^2 \mathbf{v}_1 + 2t \mathbf{v}_2 + 2 \mathbf{v}_3)\end{aligned}\quad (64)$$

Example: The only eigenvalue of the matrix  $A = \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$  is  $\lambda = 2$ , with the single (linearly independent) eigenvector  $\mathbf{v} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ . Let  $\mathbf{v}_1 = \mathbf{v}$ . To find a generalized eigenvector  $\mathbf{v}_2$ , we solve the equation

$$\begin{aligned}(A - \lambda E_n) \mathbf{v}_2 &= \mathbf{v}_1 \\ \left( \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix} - \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} \right) \mathbf{v}_2 &= \begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \mathbf{v}_2 &= \begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} &= \begin{pmatrix} 1 \\ 0 \end{pmatrix}\end{aligned}\quad (65)$$

### Inhomogeneous linear systems

## Part IV

# Dynamical Systems

### Overview

A *dynamical system* is a time-dependent process which is described by a mathematical model and whose temporal evolution is completely determined by its initial state.

The set of all possible states of a dynamical system is its *phase space*, and the temporal evolution in phase space is the *flow* of the dynamical system.

- A *continuous* dynamical system is a system of differential equations of the form

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R} \quad (67)$$

Time in such systems is in principle measured continuously. The solutions of these systems are differentiable functions. Solutions are also called *trajectories* or *orbits* of the system.

- A *discrete* dynamical system is a system of difference equations of the form

$$x_{n+1} = f(x_n) \quad (68)$$

Time in physical systems sometimes also has to be measured in discrete steps.

The solutions of this equation are sequences  $(x_n)$ .

## One-Dimensional Systems

### Fixed points

A *fixed point* of the a dynamical system is an  $x^*$  with the property

$$\dot{x} = f(x^*) = 0 \quad (69)$$

If  $x^*$  is a fixed point, then  $x(t) = x^*$  is a constant solution of the system.

For the solution  $x(t)$  of a one-dimensional system there are the following possibilities:

- The solution is a fixed point
- The solution grows monotonically, *i.e.*  $\dot{x}(t) > 0$
- The solution decays monotonically, *i.e.*  $\dot{x}(t) < 0$

Example: We consider the ODE of limited growth

$$\dot{N} = rN \left( 1 - \frac{N}{K} \right) \quad (70)$$

If  $K = 1$ ,  $\dot{N} = 0$  if  $N = 0$  and  $N = 1$  *i.e.* the fixed points are  $x_1 = 0$  and  $x_2 = 1$ .

1D-systems have no periodical Solutions

### Linear stability analysis

- stable if  $f'(x^*) < 0$ ,
- unstable, if  $f'(x^*) > 0$ ,
- stable of unstable, if  $f'(x^*) = 0$

Example:

## Two-Dimensional Systems

## Three-Dimensional Systems and Chaos
